django-contact-form provides customizable contact-form functionality for Django-powered Web sites.

Basic functionality (collecting a name, email address and message) can be achieved out of the box by setting up a few templates and adding one line to your site’s root URLconf:

```python
url(r'^contact/', include('contact_form.urls')),
```

For notes on getting started quickly, and on how to customize django-contact-form's behavior, read through the full documentation below.

Contents:
Installation guide

Before installing django-contact-form, you’ll need to have a copy of Django already installed. For information on obtaining and installing Django, consult the Django download page, which offers convenient packaged downloads and installation instructions.

The 1.4 release of django-contact-form supports Django 1.8, 1.10, and 1.11 on the following Python versions (matching the versions supported by Django itself):

- Django 1.8 supports Python 2.7, 3.3, 3.4, and 3.5.
- Django 1.10 supports Python 2.7, 3.4, and 3.5.
- Django 1.11 supports Python 2.7, 3.4, 3.5, and 3.6

**Important: Python 3.2**

Although Django 1.8 supported Python 3.2 at the time of its release, the Python 3.2 series has reached end-of-life, and as a result support for Python 3.2 has been dropped from django-contact-form.

**Normal installation**

The preferred method of installing django-contact-form is via pip, the standard Python package-installation tool. If you don’t have pip, instructions are available for how to obtain and install it. If you’re using Python 2.7.9 or later (for Python 2) or Python 3.4 or later (for Python 3), pip came bundled with your installation of Python.

Once you have pip, type:

```bash
pip install django-contact-form
```

If you plan to use the included spam-filtering contact form class, AkismetContactForm, you will also need the Python akismet module. You can manually install it via pip install akismet, or tell django-contact-form to install it for you, by running:
pip install django-contact-form[akismet]

Installing from a source checkout

If you want to work on django-contact-form, you can obtain a source checkout.

The development repository for django-contact-form is at <https://github.com/ubernostrum/django-contact-form>. If you have git installed, you can obtain a copy of the repository by typing:

```
$ git clone https://github.com/ubernostrum/django-contact-form.git
```

From there, you can use normal git commands to check out the specific revision you want, and install it using `pip install -e` (the `-e` flag specifies an “editable” install, allowing you to change code as you work on django-contact-form, and have your changes picked up automatically).

Configuration and use

Once you have Django and django-contact-form installed, check out the quick start guide to see how to get your contact form up and running.
First you’ll need to have Django and django-contact-form installed; for details on that, see *the installation guide*. Once that’s done, you can start setting up django-contact-form. Since it doesn’t provide any database models or use any other application-config mechanisms, you do *not* need to add django-contact-form to your `INSTALLED_APPS` setting; you can begin using it right away.

**URL configuration**

The quicket way to set up the views in django-contact-form is to use the provided URLconf, found at `contact_form.urls`. You can include it wherever you like in your site’s URL configuration; for example, to have it live at the URL `/contact/`:

```python
from django.conf.urls import include, url

urlpatterns = [
    # ... other URL patterns for your site ...    
    url(r'^contact/', include('contact_form.urls')),
]
```

If you’ll be using a custom form class, you’ll need to manually set up your URLs so you can tell django-contact-form about your form class. For example:

```python
from django.conf.urls import include, url
from django.views.generic import TemplateView
from contact_form.views import ContactFormView
from yourapp.forms import YourCustomFormClass

urlpatterns = [
    # ... other URL patterns for your site ...    
]
```
url(r'^contact/$',
    ContactFormView.as_view(
        form_class=YourCustomFormClass
    ),
    name='contact_form'),
url(r'^contact/sent/$',
    TemplateView.as_view(
        template_name='contact_form/contact_form_sent.html'
    ),
    name='contact_form_sent'),

---

**Important: Where to put custom forms and views**

When writing a custom form class (or custom ContactFormView subclass), **don’t** put your custom code inside django-contact-form. Instead, put your custom code in the appropriate place (a forms.py or views.py file) in an application you’ve written.

---

**Required templates**

The two views above will need two templates to be created:

**contact_form/contact_form.html** This is used to display the contact form. It has a RequestContext (so any context processors will be applied), and also provides the form instance as the context variable form.

**contact_form/contact_form_sent.html** This is used after a successful form submission, to let the user know their message has been sent. It has a RequestContext, but provides no additional context variables of its own.

You’ll also need to create at least two more templates to handle the rendering of the message: **contact_form/contact_form.txt** for the body (note that the file extension for these is .txt, not .html!). Both of these will receive a RequestContext with a set of variables named for the fields of the form (by default: name, email and body), as well as one more variable: site, representing the current site (either a Site or RequestSite instance, depending on whether Django’s sites framework is installed).

---

**Warning: Subject must be a single line**

In order to prevent header injection attacks, the subject **must** be only a single line of text, and Django’s email framework will reject any attempt to send an email with a multi-line subject. So it’s a good idea to ensure your contact_form_subject.txt template only produces a single line of output when rendered; as a precaution, however, django-contact-form will split the output of this template at line breaks, then forcibly re-join it into a single line of text.

---

**Using a spam-filtering contact form**

Spam filtering is a common desire for contact forms, due to the large amount of spam they can attract. There is a spam-filtering contact form class included in django-contact-form: AkismetContactForm, which uses the Wordpress Akismet spam-detection service.

To use this form, you will need to do the following things:
1. Install the Python akismet module to allow django-contact-form to communicate with the Akismet service. You can do this via pip install akismet, or as you install django-contact-form via pip install django-contact-form[akismet].

2. Obtain an Akismet API key from <https://akismet.com/>, and associate it with the URL of your site.

3. Supply the API key and URL for django-contact-form to use. You can either place them in the Django settings AKISMET_API_KEY and AKISMET_BLOG_URL, or in the environment variables PYTHON_AKISMET_API_KEY and PYTHON_AKISMET_BLOG_URL.

Then you can replace the suggested URLconf above with the following:

```python
from django.conf.urls import include, url

urlpatterns = [
    # ... other URL patterns for your site ...
    url(r'^contact/', include('contact_form.akismet_urls')),
]
```
There are two contact-form classes included in django-contact-form; one provides all the infrastructure for a contact form, and will usually be the base class for subclasses which want to extend or modify functionality. The other is a subclass which adds spam filtering to the contact form.

The ContactForm class

class contact_form.forms.ContactForm
    The base contact form class from which all contact form classes should inherit.
    If you don’t need any customization, you can use this form to provide basic contact-form functionality; it will collect name, email address and message.

    The ContactFormView included in this application knows how to work with this form and can handle many types of subclasses as well (see below for a discussion of the important points), so in many cases it will be all that you need. If you’d like to use this form or a subclass of it from one of your own views, here’s how:

    1. When you instantiate the form, pass the current HttpRequest object as the keyword argument request; this is used internally by the base implementation, and also made available so that subclasses can add functionality which relies on inspecting the request (such as spam filtering).

    2. To send the message, call the form’s save method, which accepts the keyword argument fail_silently and defaults it to False. This argument is passed directly to Django’s send_mail() function, and allows you to suppress or raise exceptions as needed for debugging. The save method has no return value.

    Other than that, treat it like any other form; validity checks and validated data are handled normally, through the is_valid() method and the cleaned_data dictionary.

    Under the hood, this form uses a somewhat abstracted interface in order to make it easier to subclass and add functionality.

    The following attributes play a role in determining behavior, and any of them can be implemented as an attribute or as a method (for example, if you wish to have from_email be dynamic, you can implement a method named from_email() instead of setting the attribute from_email):
from_email
The email address to use in the From: header of the message. By default, this is the value of the setting DEFAULT_FROM_EMAIL.

recipient_list
The list of recipients for the message. By default, this is the email addresses specified in the setting MANAGERS.

subject_template_name
The name of the template to use when rendering the subject line of the message. By default, this is contact_form/contact_form_subject.txt.

template_name
The name of the template to use when rendering the body of the message. By default, this is contact_form/contact_form.txt.

And two methods are involved in producing the contents of the message to send:

message()
Returns the body of the message to send. By default, this is accomplished by rendering the template name specified in template_name.

subject()
Returns the subject line of the message to send. By default, this is accomplished by rendering the template name specified in subject_template_name.

Finally, the message itself is generated by the following two methods:

get_message_dict()
This method loops through from_email, recipient_list, message() and subject(), collecting those parts into a dictionary with keys corresponding to the arguments to Django’s send_mail function, then returns the dictionary. Overriding this allows essentially unlimited customization of how the message is generated. Note that for compatibility, implementations which override this should support callables for the values of from_email and recipient_list.

get_context()
For methods which render portions of the message using templates (by default, message() and subject()), generates the context used by those templates. The default context will be a RequestContext (using the current HTTP request, so user information is available), plus the contents of the form’s cleaned_data dictionary, and one additional variable:

site If django.contrib.sites is installed, the currently-active Site object. Otherwise, a RequestSite object generated from the request.

Meanwhile, the following attributes/methods generally should not be overridden; doing so may interfere with functionality, may not accomplish what you want, and generally any desired customization can be accomplished in a more straightforward way through overriding one of the attributes/methods listed above.

request
The HttpRequest object representing the current request. This is set automatically in __init__(), and is used both to generate a RequestContext for the templates and to allow subclasses to engage in request-specific behavior.

save()
If the form has data and is valid, will send the email, by calling get_message_dict() and passing the result to Django’s send_mail function.

Note that subclasses which override __init__ or save() need to accept *args and **kwargs, and pass them via super, in order to preserve behavior (each of those methods accepts at least one additional argument, and this application expects and requires them to do so).
The Akismet (spam-filtering) contact form class

class contact_form.forms.AkismetContactForm
    A subclass of ContactForm which adds spam filtering, via the Wordpress Akismet spam-detection service.

    Use of this class requires you to provide configuration for the Akismet web service; you’ll need to obtain an
    Akismet API key, and you’ll need to associate it with the site you’ll use the contact form on. You can do this at
    <https://akismet.com/>. Once you have, you can configure in either of two ways:

    1. Put your Akismet API key in the Django setting AKISMET_API_KEY, and the URL it’s associated with
       in the setting AKISMET_BLOG_URL, or
    2. Put your Akismet API key in the environment variable PYTHON_AKISMET_API_KEY, and the URL it’s
       associated with in the environment variable PYTHON_AKISMET_BLOG_URL.

    You will also need the Python Akismet module to communicate with the Akismet web service. You can install
    it by running pip install akismet, or django-contact-form can install it automatically for you if you run
    pip install django-contact-form[akismet].

    Once you have an Akismet API key and URL configured, and the akismet module installed, you can drop in
    AkismetContactForm anywhere you would have used ContactForm. For example, you could define a
    view (subclassing ContactFormView) like so, and then point a URL at it:

```python
from contact_form.forms import AkismetContactForm
from contact_form.views import ContactFormView

class AkismetContactFormView(ContactFormView):
    form_class = AkismetContactForm
```

Or directly specify the form in your URLconf:

```python
from django.conf.urls import url
from contact_form.forms import AkismetContactForm
from contact_form.views import ContactFormView

urlpatterns = [
    # other URL patterns...
    url(r'^contact-form/$',
        ContactForm.as_view(  
            form_class=AkismetContactForm
        ),
        name='contact_form'),
]
```
class `contact_form.views.ContactFormView`

The base view class from which most custom contact-form views should inherit. If you don’t need any custom functionality, and are content with the default `ContactForm` class, you can also use it as-is (and the provided URLConf, `contact_form.urls`, does exactly this).

This is a subclass of Django’s `FormView`, so refer to the Django documentation for a list of attributes/methods which can be overridden to customize behavior.

One non-standard attribute is defined here:

**recipient_list**

The list of email addresses to send mail to. If not specified, defaults to the `recipient_list` of the form.

Additionally, the following standard (from `FormView`) methods and attributes are commonly useful to override (all attributes below can also be passed to `as_view()` in the URLconf, permitting customization without the need to write a full custom subclass of `ContactFormView`):

**form_class**

The form class to use. By default, will be `ContactForm`. This can also be overridden as a method named `form_class()`; this permits, for example, per-request customization (by inspecting attributes of `self.request`).

**template_name**

The template to use when rendering the form. By default, will be `contact_form/contact_form.html`.

**get_success_url()**

The URL to redirect to after successful form submission. By default, this is the named URL `contact_form.sent`. In the default URLconf provided with django-contact-form, that URL is mapped to `TemplateView` rendering the template `contact_form/contact_form_sent.html`.

**get_form_kwargs()**

Returns additional keyword arguments (as a dictionary) to pass to the form class on initialization.

By default, this will return a dictionary containing the current `HttpRequest` (as the key `request`) and, if `recipient_list` was defined, its value (as the key `recipient_list`).
**Warning:** If you override `get_form_kwargs()`, you **must** ensure that, at the very least, the keyword argument `request` is still provided, or `ContactForm` initialization will raise `TypeError`. The easiest approach is to use `super()` to call the base implementation in `ContactFormView`, and modify the dictionary it returns.
Frequently asked questions

The following notes answer some common questions, and may be useful to you when installing, configuring or using django-contact-form.

What versions of Django and Python are supported?

As of django-contact-form 1.4, Django 1.8, 1.10, and 1.11 are supported, on Python 2.7, 3.3, (Django 1.8 only), 3.4, 3.5, or 3.6 (Django 1.11 only). Although Django 1.8 supported Python 3.2 at initial release, Python 3.2 is now at its end-of-life and django-contact-form no longer supports it.

What license is django-contact-form under?

django-contact-form is offered under a three-clause BSD-style license; this is an OSI-approved open-source license, and allows you a large degree of freedom in modifying and redistributing the code. For the full terms, see the file LICENSE which came with your copy of django-contact-form; if you did not receive a copy of this file, you can view it online at <https://github.com/ubernostrum/django-contact-form/blob/master/LICENSE>.

Why aren’t there any default templates I can use?

Usable default templates, for an application designed to be widely reused, are essentially impossible to produce; variations in site design, block structure, etc. cannot be reliably accounted for. As such, django-contact-form provides bare-bones (i.e., containing no HTML structure whatsoever) templates in its source distribution to enable running tests, and otherwise just provides good documentation of all required templates and the context made available to them.
**Why am I getting a bunch of BadHeaderError exceptions?**

Most likely, you have an error in your `ContactForm` subclass. Specifically, one or more of `from_email`, `recipient_list` or `subject()` are returning values which contain newlines.

As a security precaution against email header injection attacks (which allow spammers and other malicious users to manipulate email and potentially cause automated systems to send mail to unintended recipients), Django’s email-sending framework does not permit newlines in message headers. `BadHeaderError` is the exception Django raises when a newline is detected in a header.

Note that this only applies to the headers of an email message; the message body can (and usually does) contain newlines.

**I found a bug or want to make an improvement!**

The canonical development repository for django-contact-form is online at https://github.com/ubernostrum/django-contact-form. Issues and pull requests can both be filed there.

If you’d like to contribute to django-contact-form, that’s great! Just please remember that pull requests should include tests and documentation for any changes made, and that following PEP 8 is mandatory. Pull requests without documentation won’t be merged, and PEP 8 style violations or test coverage below 100% are both configured to break the build.

**I’m getting errors about “akismet” when trying to run tests?**

The full test suite of django-contact-form exercises all of its functionality, including the spam-filtering `AkismetContactForm`. That class uses the Wordpress Akismet spam-detection service to perform spam filtering, and so requires the Python `akismet` module to communicate with the Akismet service, and some additional configuration (in the form of a valid Akismet API key and associated URL).

By default, the tests for `AkismetContactForm` will be skipped unless the required configuration (in the form of either a pair of Django settings, or a pair of environment variables) is detected. However, if you have supplied Akismet configuration but do not have the Python `akismet` module, you will see test errors from attempts to import `akismet`. You can resolve this by running:

```
pip install akismet
```

or (if you do not intend to use `AkismetContactForm`) by no longer configuring the Django settings/environment variables used by Akismet.

Additionally, if the `AkismetContactForm` tests are skipped, the default code-coverage report will fail due to the relevant code not being exercised during the test run.
